## Semantics of a first-order language

## Interpretations

An interpretation $\mathcal{I}$ is a pair $(D, I)$, where $D \neq \emptyset$ is a set (the domain of the universe) and $I$ maps symbols to individuals or functions

- constants: $I(a)=d \in D$
- variables: $I(x)=d \in D$
- functions: $I(f / n)=\mathcal{F}: D^{n} \mapsto D$
- $I\left(f\left(t_{1}, \ldots, t_{n}\right)\right)=\mathcal{F}\left(I\left(t_{1}\right), \ldots, I\left(t_{n}\right)\right)=\mathcal{F}\left(d_{1}, \ldots, d_{n}\right) \in D$
- predicates: $I(p / n)=\mathcal{P}: D^{n} \mapsto\{\mathbf{t}, \mathbf{f}\}$

$$
\text { - } I\left(p\left(t_{1}, \ldots, t_{n}\right)\right)=\mathcal{P}\left(I\left(t_{1}\right), \ldots, I\left(t_{n}\right)\right)=\mathcal{P}\left(d_{1}, \ldots, d_{n}\right) \in\{\mathbf{t}, \mathbf{f}\}
$$

- an interpretation assigns an element of $D$ to any term, and a truth value to any predicate applied to terms
- $\mathcal{P}$ is an $n$-ary relation $\mathcal{R}: \mathcal{P}\left(d_{1}, \ldots, d_{n}\right)=\mathbf{t}$ iff $\left\langle d_{1}, \ldots, d_{n}\right\rangle \in \mathcal{R}$

## Semantics of a first-order language

## Evaluation of a formula

Assigning a truth value to a formula, according to:

- The chosen interpretation of constants, functions and predicates
- The rules for evaluation (see also truth tables)

$$
\begin{array}{lll}
I(\neg F)=\mathbf{t} & \text { iff } & I(F)=\mathbf{f} \\
I(F \wedge G)=\mathbf{t} & \text { iff } & I(F)=I(G)=\mathbf{t} \\
I(F \vee G)=\mathbf{f} & \text { iff } & I(F)=I(G)=\mathbf{f} \\
I(F \rightarrow G)=\mathbf{f} & \text { iff } & I(F)=\mathbf{t} \text { and } I(G)=\mathbf{f} \\
I(F \leftrightarrow G)=\mathbf{t} & \text { iff } & I(F)=I(G) \\
I(\forall x F(x))=\mathbf{t} & \text { iff } & I(F(x / c))=\mathbf{t}
\end{array} \text { * for every constant } c_{I(\exists x F(x))=\mathbf{t}} \text { iff } \quad I(F(x / c))=\mathbf{t}{ }^{*} \text { for at least one constant } c .
$$

I (instead of $\mathcal{I}$ ) will often denote an interpretation when $D$ is clear

## Semantics of a first-order language

Example (propositional): $(p \rightarrow q) \wedge(q \rightarrow r) \rightarrow r$

- first interpretation: $I^{\prime}(p)=\mathbf{f}, I^{\prime}(q)=\mathbf{f}, I^{\prime}(r)=\mathbf{t}$

- second interpretation: $I^{\prime \prime}(p)=\mathbf{f}, I^{\prime \prime}(q)=\mathbf{f}, I^{\prime \prime}(r)=\mathbf{f}$

## Semantics of a first-order language

Example (propositional): $(p \rightarrow q) \wedge(q \rightarrow r) \rightarrow r$

- this example only needs truth tables, for all possible interpretations

| $p$ | $q$ | $r$ | $p \rightarrow q$ | $q \rightarrow r$ | $(p \rightarrow q) \wedge(q \rightarrow r)$ | $(p \rightarrow q) \wedge(q \rightarrow r) \rightarrow r$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ |

## Semantics of a first-order language

## Example (first-order): $\forall x(m(a, x) \wedge p(x)) \rightarrow \forall y q(s(y))$

- first interpretation: $D=\{0,1,2,3, .$.
- $I(a)=0$
- $I(s(x))=\mathcal{S}(I(x))=$ the successor of $I(x)$
- $p(x)$ means that $x$ is even
- $q(x)$ means that $x$ is odd
- $m(x, y)$ means that $x<y$
- $\mathcal{I}$ evaluates the formula to $\mathbf{t}$ (try it!)

## Semantics of a first－order language

Example（first－order）：$\forall x(m(a, x) \wedge p(x)) \rightarrow \forall y q(s(y))$

| ${ }^{x}$ | $s(x)$ |  | $p(x)$ |  | $q(x)$ | $m$ | 罳 |  | " |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 骨 | $\mathrm{F}_{\mathrm{ck}}^{\mathrm{cog}}$ | 定 | t | R | t | $\frac{m}{8}$ |  |  |  |
|  | Sis | 兌荡 | t |  | f |  | t | t | t |
| 5 | $\stackrel{3}{3}$ | F | t | "\% | t | $8$ | f | f | f |

－and this evaluates to $\mathbf{f}(\mathbf{t} \rightarrow \mathbf{f}=\mathbf{f})$

## Semantics of a first-order language

## Satisfiable formulæ

An interpretation $\mathcal{I}=(D, I)$ satisfies a formula $F$ on $D$ iff $I(F)=\mathbf{t}$ (also written $\mathcal{I}(F)=\mathbf{t})$. In this case, $\mathcal{I}$ is a model of $F$

- $F$ is satisfiable (written $\operatorname{SAT}(F)$ ) iff it has at least one model
- $F$ is unsatisfiable (written UNSAT $(F)$ ) iff it has no models
- that is, all interpretations are countermodels
- $F$ is valid (written $\operatorname{VAL}(F)$ ) iff every interpretation is a model
- this is denoted by $\models F$, and amounts to say $\operatorname{UNSAT}(\neg F)$

With a set of formulæ $\left\{F_{1}, . ., F_{n}\right\}$ :

- $(D, I)$ satisfies $\left\{F_{1}, . ., F_{n}\right\}$ iff $I\left(F_{i}\right)=\mathbf{t}$ on $D$ for every $i$
- $\left\{F_{1}, . ., F_{n}\right\}$ is satisfiable iff there is such an interpretation

Example: $\forall x(m(a, x) \wedge p(x)) \rightarrow \forall y q(s(y))$
This formula is satisfiable but not valid

## Logical consequence

## Logical consequence

Given a set of formulæ $\Gamma=\left\{F_{1}, . ., F_{n}\right\}$ and a formula $G$ over the same language, $G$ is a logical consequence of $\Gamma$ (written $\Gamma \models G)$ iff every interpretation satisfying $\Gamma$ also satisfies $G$, or, equivalently, there is no interpretation which satisfies $\Gamma$ but not $G$

## Important (in some sense, it is a matter of convenience)

$$
\left\{F_{1}, . ., F_{n}\right\} \models G \quad \text { iff } \quad \vDash\left(F_{1} \wedge . . \wedge F_{n}\right) \rightarrow G
$$

## To decide $\Gamma \models G$ can be very hard

We have to take all models of $\Gamma$ and verify that they all satisfy $G$, or find a counterexample

## Logical consequence

Example: $\{p \rightarrow(q \rightarrow r), p \wedge q\} \models r$
Equivalent to $=((p \rightarrow(q \rightarrow r)) \wedge(p \wedge q)) \rightarrow r$

| $p$ | $q$ | $r$ | $p \rightarrow(q \rightarrow r)$ | $p \wedge q$ | $(p \rightarrow(q \rightarrow r)) \wedge(p \wedge q)$ | $G$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |

## Logical consequence

Example: $\{p \rightarrow(q \rightarrow r), p \wedge q\} \models \neg r$
Equivalent to $=((p \rightarrow(q \rightarrow r)) \wedge(p \wedge q)) \rightarrow \neg r$

| $p$ | $q$ | $r$ | $p \rightarrow(q \rightarrow r)$ | $p \wedge q$ | $(p \rightarrow(q \rightarrow r)) \wedge(p \wedge q)$ | $G$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ |
| $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |
| $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ | $\mathbf{f}$ | $\mathbf{f}$ | $\mathbf{t}$ |

## Logical consequence

## Example: $\{\exists x p(x), \exists x q(x)\} \models \exists x(p(x) \wedge q(x))$

- $D=\{1,2,3,4, .$.
- $p(x): x$ is even
- $q(x): x$ is odd

It is easy to see that this interpretation makes both premises true (indeed, there exist even numbers and there exist odd numbers), but does not satisfy the conclusion (no numbers are both even and odd)

$$
I(\exists x p(x))=\mathbf{t} \quad I(\exists x q(x))=\mathbf{t} \quad I(\exists x(p(x) \wedge q(x)))=\mathbf{f}
$$

Therefore, the deduction is incorrect

Example: $\{\exists x p(x), \exists x q(x)\} \models \exists x(p(x) \vee q(x))$
This is, of course, a valid deduction

## Syntax vs. semantics

## Formal systems

A proof formal system consists of:

- a formal language (alphabet and rules for building formulæ)
- a set of logical axioms (i.e., valid formulæ, which do not require proof)
- a set of inference rules for proving new formulæ
- a definition of proof

## Theories

A theory $T$ is a formal system extended with a set $\Gamma$ of non-logical axioms (i.e., formulæ taken for granted) $\rightsquigarrow \quad T[\Gamma]$

- if $\Gamma=\emptyset$, then $T$ is the basic theory of the formal system

## Syntax vs. semantics

## Proofs

A proof of a formula $G$ in a theory $T[\Gamma]$ (written $T[\Gamma] \vdash G)$ is a finite sequence of formulæ such that each formula of the sequence is either

- a logical or non-logical axiom of the theory; or
- the result of applying an inference rule to previous formulæ in the sequence and $G$ is the last formula in the sequence

## Theorems

A theorem is a formula for which there is at least one proof

## Arguments

An argument with premises $A_{1}, . ., A_{n}$ and conclusion $B$ is logically correct in a formal system if $T\left[A_{1}, . ., A_{n}\right] \vdash B$

## Syntax vs. semantics

## Proof example: $T[p \rightarrow(q \rightarrow r), p \wedge q] \vdash r$

```
(1) \(p \rightarrow(q \rightarrow r)\)
(2) \(\neg p \vee(\neg q \vee r)\)
(3) \((\neg p \vee \neg q) \vee r\)
(4) \(\neg(p \wedge q) \vee r\)
(5) \(p \wedge q \rightarrow r\)
(6) \(p \wedge q\)
(7) \(r\)
```

first premise interdefinition of $\rightarrow$, $\neg$ and $\vee$ on $(1$ associativity on (2)
De Morgan on (3
interdefinition of $\rightarrow$, $\neg$ and $\vee$ on (4)
second premise
modus ponens on 6, $\mathbf{6}$

## Another approach to prove validity

Instead of looking at all the possible models of a formula, we exploited our knowledge of logical rules

- we also say that $\quad((p \rightarrow(q \rightarrow r)) \wedge(p \wedge q)) \rightarrow r \quad$ is a tautology

## Syntax vs. semantics

## Theorem (Deduction)

$T\left[F_{1}, . ., F_{n}\right] \vdash G \quad$ iff $\quad T \vdash\left(F_{1} \wedge . . \wedge F_{n}\right) \rightarrow G$

- question: why do we use both forms (premises and implication)?

## Theorem (Validity)

Every theorem of $T$ is logically valid: if $T \vdash G$ then $\models G$

- this happens if the formal system is consistent! $\rightsquigarrow$ Gödel

## Theorem (Completeness)

In a first-order theory $T$, all valid formulæ are theorems of $T$ : if $\models G$ then $T \vdash G$

- the rest of the course will be basically about finding such theorems

## Syntax vs. semantics

Theorem (Deduction, equivalent form)
$T\left[F_{1}, . ., F_{n}\right] \vdash G \quad$ iff $\quad \operatorname{VAL}\left(\left(F_{1} \wedge . . \wedge F_{n}\right) \rightarrow G\right)$

- question: why do we use both forms (premises and implication)?

## Theorem (Validity)

Every theorem of $T$ is logically valid: if $T \vdash G$ then $\models G$

- this happens if the formal system is consistent! $\rightsquigarrow$ Gödel

## Theorem (Completeness)

In a first-order theory $T$, all valid formulæ are theorems of $T$ : if $\models G$ then $T \vdash G$

- the rest of the course will be basically about finding such theorems
